AIR-TO-SF₆ - Gas-insulated bushing

IEC STANDARDS 60137 - ANSI STANDARDS

PABS bushings are gas-insulated types that meet IEC 60137, ANSI/IEEE or other National Standards. They are designed for connection, in any ambient conditions, of GIS, GIL or Dead Tank Circuit Breakers to overhead transmission lines.

According to the operating temperature, the gas used for filling is pure SF₆ or a mixture of SF₆ and N₂.

The bushing is designated as follows:
PABS.420.1425.4000.X

- **PABS**: Gas-insulated bushings, air-to-SF₆ application
- **420**: Insulation class in kV
- **1425**: BIL in kV
- **4000**: Rated current in A

**Voltage and current ratings**

Standard rated voltage, at 50/60Hz, is:
- 72.5 kV to 800 kV for composite design
- 72.5 kV to 500 kV for porcelain design

Standard rated current is 2000 A through 5000 A, according to the rated voltage; it is possible to realize bushings up to 8000 A. For non-standard ratings, consult Passoni & Villa.

**Customer Benefits**

- Bushings with longer lifetime and higher reliability
- Explosion and fire-proof design
- Non-aging internal insulation
- Installation in any position
- On line monitoring in service
Main Features

PABS: IEC and ANSI Standards gas-insulated bushings

- Range 72.5 to 800 kV
- High continuous withstand current up to 8000 A
- High short-circuit current up to 100 kA - 1s; 63kA - 3s
- Gas-insulated bushings with pure SF₆ or SF₆-N₂ mixture
- Non-aging internal insulation
- Air side: porcelain or composite insulator
- Standard design as common gas zone with GIS/GIL
- Explosion and fire-proof design
- High quality sealing system and efficient gas leakage control: gas leakage less than 0.5% per year (usual ≤ 0.1%)
- Installation in any position
- In-service monitoring of main gas insulation through density (pressure) control
- Polyester-varnished aluminum flanges

Design

Standard bushing type PABS are designed with gas zone in common with GIS/GIL or HV CB gas compartments. The accessories like filling plug, insulator support (barrier) and pressure relief device are at GIS/GIL manufacturer care. Main internal insulation is pure SF$_6$ or a mixture of SF$_6$/N$_2$ at proper density (measured as gas pressure at 20°C - 68°F), while external insulation is provided by the high strength porcelain or composite insulator. Bushings up to and including 362 kV are designed with internal screen(s), while bushings at 420 kV and above are designed with internal semi-graded insulation made of gas-impregnated synthetic films (patent pending). This solution grants compact dimensions with more uniform internal/external electric field distribution.

If required, all bushings, at 420 kV and above, can be equipped with a voltage tap and an associated voltage indicator. With the proper capacitance design, it is possible to achieve the low voltage $U_2$ (few tens of volts) for indicators or measuring devices. Bushings at 420 kV and above can also be provided, with test tap for tan $\delta$, capacitance and partial discharges quantity measurement. During service, if not used, voltage tap must be grounded by using the voltage tap cap.

Manufacturing

All manufacturing procedures (certified to EN 29001 - ISO 9001) comply with the Passoni & Villa Quality Assurance System and procedures. The manufacturing process for PABS bushings is shorter than oil-insulated bushings thanks to the lower sensitivity of SF$_6$ insulation to humidity and air presence. The assembling is made in a pure and unpolluted ambient in order to avoid internal insulation contamination. For bushings manufactured with porcelain envelopes, both sides of the porcelain are cemented to the metal flanges (see fig. 5).

All cemented surfaces, potentially in contact with the external environment, are silicone sealed. For bushings manufactured with a composite insulator, the fiberglass tube is tightly glued to the metal flanges, and a unique silicon cast realizes the sealing and the sheds for the requested creepage distance. Before factory tests, bushings are treated under vacuum and then filled with gas at minimum operating pressure.

Terminals and conductor

The cylindrical top terminal is made of aluminum or copper and is fixed to the upper closing plate. Different terminals, such as NEMA types, are available upon request. The main conductor is a central rod made of aluminum or copper according to the rated current. The bottom terminal connection to the GIS/GIL or CB is silver plated or copper plated. Its dimensions and shape are designed according to the customers request.
Air side

The external insulator is made of brown porcelain, (grey upon request) with cemented flanges, or composite insulator (resin fiberglass envelope covered by silicone sheds) glued to the metal parts. This system offers high mechanical strength during normal and above-normal service conditions. The alternating shed configuration (short-long sheds) is the most effective solution and has been proven by salt spray tests. The shed profile complies with the new IEC 60815 recommendations.

Composite insulators are recommended for all Bushings from 245 kV through 800 kV, as it significantly improves bushing reliability throughout its lifetime. Other benefits include:

- better behavior against weather elements, such as pollution and rain, due to the hydrophobic property of silicon rubber
- high mechanical withstand in case of impact, shocks and/or vibrations during handling, transportation or in service, such as for seismic activity
- higher safety for personnel and equipment in case of an internal fault (explosion-proof design).

Flange

Dimensions, flange type and lower conductor terminals, are designed in order to match the dimensions of the GIS/GIL or CB conductor. For Dead-Tank Circuit Breaker installation, thoroidal cores for measurement and protection, according to ANSI/IEEE, IEC or other National Standards, are supplied on request.

Insulation

The basic insulation is Sulphur-hexafluoride (SF₆), which is not poisonous no flammable and has good dielectric, arc-extinguishing and thermal capabilities. These characteristics enables it to be widely used in MV and HV equipments. The insulation characteristic of SF₆ depends on the internal apparatus density and can be expressed in bar (PSI) at a temperature of 20 °C (68 °F). At approx. 3 bar (43.5 PSI) SF₆ gas has the same dielectric strength as oil and several times higher than air.

The main SF₆ insulating features are:

- non aging
- compressibility
- less sensitivity to humidity and air
- possibility of controlling the dielectric strength through the control of SF₆ gas density (pressure).

Thanks to these characteristics, Air-to-SF₆ bushings have a long life and a very high service reliability. In case of very low ambient temperatures (down to -40 °C/-40 °F) a mixture of SF₆ and N₂ is used.

Gaskets

The sealing system is of fundamental importance for any pressurized equipment. Specifically, it has to guarantee leakage of less than 0.5 % per year. For this purpose Passoni & Villa has a very severe regulation and tolerances concerning the choice, control and tests of gaskets and their grooves (i.e. material, resistance to high temperatures, ozone, radiation and other ambient contaminants that may influence the aging process of the gaskets). Our internal standards permit the leakage less than 0.1 % per year. O-ring type gaskets are made of EPDM which grants the usage in a wide range of temperatures: from -45 °C to +150 °C. With our double-gasket system, flange and grooves are lubricated with a special grease in order to guarantee the highest tightness and to prevent corrosive influences in severe ambient conditions.
**Metal surface treatment**

Upon request, according to specific customer requirements, finishing or final painting can be provided.

**Tests**

Type and routine tests are performed according to the latest edition of IEC 60137 or ANSI/IEEE Standards or other specific requirements. Important leakage tests assure service reliability. By measuring total leakage using a highly sensitivity leak-meter ("Qm" method in accordance with IEC 68-2-17/94) we guarantee a leakage of less than 0.5 % per year, but normally it is less than 0.1 %.

In addition to routine and type tests prescribed by Standards, bushings from 420 kV through 800 kV are subjected to the Very Fast Transient (VFT) withstand tests.

In order to verify the bushing electrical withstand capability the bushing with semi-graded internal insulation is tested with lightning impulses chopped in SF$_6$, this simulating possible flashovers in GIS during its on-site tests according to IEC 62271-102 standard.

The repetition of type tests is performed in order to guarantee that the bushing has preserved all its characteristics after VFT tests.

**Packing - Transportation**

All bushings are protected with a plastic envelope and are horizontally transported in wooden cases. Bushings up to and including 170 kV are usually shipped in crates containing three pieces, while crates containing a single piece are used for higher voltages.

During transportation, the lower part of the bushing is closed and protected by a transport cover which is used also for fixing the central conductor. Bushings at 420 kV and above are transported with a relatively small overpressure of dry nitrogen (0.2-0.3 bar). The gas zone is filled through the automatic non-return valve.

**Gas filling and refilling**

After the bushing is connected to the network and before energizing, it has to be vacuum treated together with the GIS/GIL or CB and then filled with gas. For filling, use pure SF$_6$ gas or a mixture of SF$_6$ and N2 according to the prescription of the Standards (IEC 60378 or other National Standard).
